## Abstract

---

5G looms over the network strategies of mobile operators, as does the ongoing move toward Cloud RAN (CRAN), software defined networking (SDN) and network function virtualization (NFV). All of this – along with many other factors – drives the need for reliable, scalable and cost effective fronthaul and backhaul.

Fiber is the primary physical medium for transporting control and user plane traffic among cell sites, the edge, the mobile core, data centers and the Internet. Wireless solutions have their place and scale reasonably well, but as traffic shifts from LTE to 5G and as mobile data demand grows, fiber is likely to remain the key medium for transporting user data (and control plane data) from cell sites to the core network. This is backhaul.

Remote radio heads (RRHs) are the mainstay of most RANs. Fiber links the RRHs to the baseband processing units (BBUs) at the bottom of the tower. This is fronthaul. Increasingly, those BBUs are being centralized at a place other than the bottom of each macrocell tower. The current technology of choice for linking BBUs and radios is CPRI. BBU centralization is the first step on the road toward Cloud RAN (C-RAN).

But, CPRI does not scale into tomorrow's world of MIMO and Massive MIMO. The amount of bandwidth required to transport CPRI signals (digitized version of analog radio traffic) scales in relation to the number of radios, and on a cell site with dozens of antennas (and radios) the amount of throughput required would quickly scale into the terabytes per second. And while this might technically be possible with fiber and multiplexing (WDM), the cost would likely be prohibitive.

So, in the last few years, there has been a push to, essentially, rethink CPRI and create a new “functional split” between the radio and the baseband processing. There are multiple efforts underway to define a new standard (eCPRI, NGFI, Fronthaul Lite) and it appears likely that some version of the functional split will become part of the 3GPP standards releases. Essentially the goal of the functional split concept is to minimize the amount of traffic that has to pass over the fronthaul links. This market study provides an overview of the different efforts to that end.

This market study also provides a five-year forecast of the number of front/backhaul links to cell sites by type of medium (fiber, copper, or wireless) and by type of cell (macrocell or outdoor small cell). Finally, it forecasts the amount of mobile data demand that flows over those links by generation (5G and non-5G).

Key questions addressed in this study:

- What is the anticipated growth of front/backhaul in the U.S. through 2022?
- How is traffic split between 4G LTE and 5G?
- What is the difference between fronthaul and backhaul?
- How is the type of front/backhaul split between fiber, wireless and copper?
- What is the forecast for front/backhaul to support outdoor small cell deployments?
- What are the major concerns of the mobile operators with regard to each type of backhaul and how can these concerns be addressed?
- What is the role for wired and wireless front/backhaul in small cell architectures?
- How is wired and wireless front/backhaul deployed?
- How do PTP, PMP, NLOS, millimeter wave and traditional microwave solutions differ?
- How do fiber (point to point and passive), VDSL2 and coaxial (hybrid fiber coax) differ?
- How does wireless backhaul compare to fiber backhaul?
- How does wireless fronthaul compare to fiber fronthaul?
- What is CPRI and how may it change?

This report is recommended for:

- Mobile operators, particularly those servicing the U.S. market
- Mobile backhaul providers, including telcos and cable MSOs
- Wired and wireless backhaul vendors and solution providers
- Mobile OEMs, particularly those servicing the U.S. market
- Wired and wireless infrastructure vendors, particularly those servicing the U.S. market
- Financial and investment analysts.
